Conclusions

Audio Segmentation and Sound Event Detection

The goal of automatic sound event detection (SED) methods is to recognize what is happening in an audio signal and when it is happening¹. In practice, the goal is to recognize at what temporal instances different sounds are active within an audio signal. An example of sound event detection is presented below.

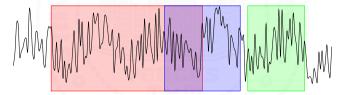

Figure 1: Event Detection in an audio track.

Introduction

¹Annamaria Mesaros et al. "Sound Event Detection: A tutorial". In: *IEEE Signal Processing Magazine* 38 (2021), pp. 67–83. URL: https://api.semanticscholar.org/CorpusID: 235795366.

Datasets

Introduction

Common datasets for Audio Segmentation and Sound Event Detection problems are:

- TUT Sound Event Detection: primarily consists of street recordings with traffic and other activity, with audio examples of 2.56s and a total size of approximately 1.5 h. It has six unique audio classes – Brakes Squeaking, Car. Children, Large Vehicle, People Speaking, and People Walking:
- Urban-SED: purely synthetic dataset, with audio example of 10s and a total size of about 30 h. It has ten unique audio classes – Air Conditioner, Car Horn, Children Playing, Dog Bark, Drilling, Engine Idling, Gun Shot, Jackhammer, Siren, and Street Music.

The first dataset is too small to train a Neural Network model and requires use of augmentation techniques (we used **SpecAugment**²).

²Daniel S. Park et al. "SpecAugment: A Simple Data Augmentation Method for Automatic Speech Recognition". In: Interspeech 2019. 2019, pp. 2613–2617. DOI: 10.21437/Interspeech.2019-2680.

Metrics

A popular toolbox for Sound Event Detection models evaluation is SED Eval³.

$$\begin{aligned} \text{Precision} &= \frac{\text{TP}}{\text{TP} + \text{FP}} & \text{Recall} &= \frac{\text{TP}}{\text{TP} + \text{FN}} \\ & F_{1}\text{-score} &= 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \end{aligned}$$

where TP, FP and FN are respectively (for each audio segment):

- the ground truth and system output both indicate an event to be active;
- the ground truth indicates an event to be inactive, but the system as active;
- the ground truth indicates an event to be active, but the system as inactive.

YOHO model

Presented in 2021, **YOHO**⁴ is a novel and lightweight real-time algorithm for *audio* segmentation and sound event detection:

- it aims to detect acoustic classes and their temporal boundaries by treating the problem as a **regression task**;
- inspired by YOLO algorithm for machine vision.

⁴Satvik Venkatesh, David Moffat, and Eduardo Reck Miranda. "You Only Hear Once: A YOLO-like Algorithm for Audio Segmentation and Sound Event Detection". In: *Applied Sciences* 12.7 (Mar. 2022), p. 3293. ISSN: 2076-3417. DOI: 10.3390/app12073293. URL: http://dx.doi.org/10.3390/app12073293.

Input shape

We feed the network a mel-spectrogram: a compressed time-frequency representation of audio signal that allows the model to better capture relevant audio patterns.

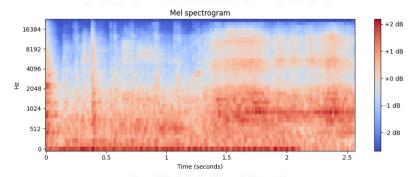

Figure 2: An example of mel-spectrogram.

Network Architecture

- Input layer: mel-spectrogram derived from the audio signal.
- MobileNet Backbone: It consists of alternating depthwise and pointwise convolution layers, which significantly reduce the number of parameters and computational complexity. This efficient design makes it ideal for real-time applications where both speed and low resource consumption are critical.
- Additional layers: these are designed to refine the feature maps extracted by the backbone, adjusting the representation to better suit the sound event detection task.

The final activation in the YOHO model is a sigmoid function, facilitating the interpretation of predictions as probabilities for sound event detection.

Output shape

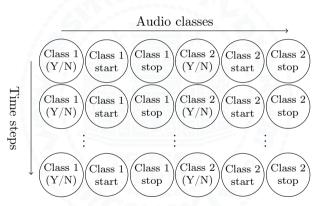

Figure 3: The YOHO output shape.

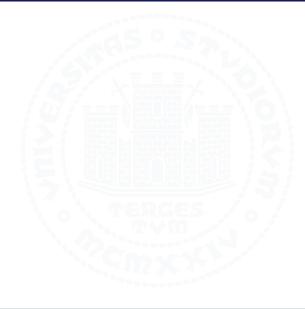

Loss Function

$$\mathcal{L}_c(\hat{y}, y) = \begin{cases} (\hat{y}_1 - y_1)^2 + \\ (\hat{y}_2 - y_2)^2 + (\hat{y}_3 - y_3)^2 & \text{if } y_1 = 1 \\ (\hat{y}_1 - y_1)^2, & \text{if } y_1 = 0 \end{cases}$$

where y and \hat{y} are the ground-truth and predictions respectively. $y_1 = 1$ if the acoustic class is present and $y_1 = 0$ if the class is absent. y_2 and y_3 , which are the start and endpoints for each acoustic class are considered only if y = 1. In other words, $(\hat{y}_1 - y_1)^2$ corresponds to **the classification loss** and $(\hat{y}_2 - y_2)^2 + (\hat{y}_3 - y_3)^2$ corresponds to **the regression loss**.

Other Details

Implementation challenges

Starting from the original paper, we implemented the system using PvTorch⁵, writing the code keeping in mind that it had to be clear and permit reproducible tests.

Work done and results

```
python3 -m voho.train --help
usage: train.py [-h] [--name NAME] [--epochs EPOCHS] [--batch-size BATCH_SIZE] [--cosine-annealing]
[--autocast] [--spec-augment]
options:
  -h, --help
                        show this help message and exit
  --name NAME
                        The name of the model
  --epochs EPOCHS
                        The number of epochs to train the model
  --batch-size BATCH_SIZE
                        The batch size for training the model
                        Use cosine annealing learning rate scheduler
  --cosine-annealing
                        Use autocast to reduce memory usage
  --autocast
                        Augment the training data using SpecAugment
  --spec-augment
```

Listing 1: Training script parameters

We used ORFEO⁶ computational resources for the trainings of the models.

⁵All the code is available at https://github.com/enstit/YOHO24.
